

## 2015 MAT Paper - Q3 (4 pages; 24/9/20)

(i) [We can of course look ahead in the question, to see what sort of functions might be used.]

$$f(x) = x, \quad g(x) = x + \frac{1}{100}$$

$$(ii) |f(x) - g(x)| = \frac{1}{400} \sin(4x^2) \text{ when } 0 \leq x \leq \frac{1}{2}$$

$$\text{(as } 4\left(\frac{1}{2}\right)^2 = 1 < \pi, \text{ so that } \sin(4x^2) > 0$$

$$\text{and } \frac{1}{400} \sin(4x^2) \leq \frac{1}{400} \sin(1) < \frac{1}{400} \sin\left(\frac{\pi}{3}\right) = \frac{1}{400} \left(\frac{\sqrt{3}}{2}\right)$$

$$= \frac{1}{320} \left(\frac{320\sqrt{3}}{800}\right) = \frac{1}{320} \left(\frac{4\sqrt{3}}{10}\right)$$

$$< \frac{1}{320} \left(\frac{4 \times 1.8}{10}\right) = \frac{1}{320} (0.72) < \frac{1}{320}$$

$$(iii) g(x) = 1 + \int_0^x 1 + t + \frac{t^2}{2} + \frac{t^3}{6} dt$$

$$= 1 + \left[ t + \frac{t^2}{2} + \frac{t^3}{6} + \frac{t^4}{24} \right]_0^x$$

$$= 1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24}$$

$$\text{Then } |f(x) - g(x)| = \frac{x^4}{24} \leq \frac{1}{16(24)} = \frac{1}{384} < \frac{1}{320} \text{ when } 0 \leq x \leq \frac{1}{2}$$

$$(iv) \text{ RHS} = g(x) - f(x) + \int_0^x (h(t) - f(t)) dt$$

$$= 1 + \int_0^x f(t) dt - f(x) + \int_0^x h(t) dt - \int_0^x f(t) dt$$

$$= 1 + \int_0^x h(t)dt - f(x) = h(x) - f(x) = \text{LHS}$$

(v) [This is a stand-alone result; ie not needing to be derived from the earlier results.]

Consider the area under the graph of  $h(t) - f(t)$ , between 0 &  $x$ .

Assume for the moment that the graph lies above the  $t$ -axis.

The maximum height of the function is  $h(x_0) - f(x_0)$ , and the area under the graph is no greater than the rectangle with base  $x$  and height  $h(x_0) - f(x_0)$ .

As  $x \leq \frac{1}{2}$ , the rectangle has area  $\leq \frac{1}{2}(h(x_0) - f(x_0))$ .

As the integral would have a smaller value if part of the graph were to lie below the  $t$ -axis,

$$\int_0^x (h(t) - f(t))dt \leq \frac{1}{2}(h(x_0) - f(x_0)) \text{ whenever } 0 \leq x \leq \frac{1}{2}$$

(vi) Result to prove:  $|f(x) - h(x)| \leq \frac{1}{100}$  for  $0 \leq x \leq \frac{1}{2}$

or, as we are told that  $f(x) \leq h(x)$ ,

and if we set  $k(x) = h(x) - f(x)$ ,

result to prove is  $k(x) \leq \frac{1}{100}$

From (iv), using (iii) & (v),

$$k(x) \leq \frac{1}{320} + \frac{1}{2}k(x_0) \quad (\text{A})$$

(since, from the working of (iii),  $g(x) > f(x)$ , so that

$$g(x) - f(x) = |g(x) - f(x)| \leq \frac{1}{320})$$

Also,  $k(x) \leq k(x_0) \quad (\text{B})$

[At first sight, this doesn't look promising, as the inequalities in (A) & (B) seem to be in unfavourable directions:

$k(x) \leq \frac{1}{320} + \frac{1}{2}k(x_0) \Rightarrow k(x_0) \geq 2k(x) - \frac{1}{160}$  , but this can't be usefully combined with (B).

However, if we consider a simple example of a graph of  $k(x)$ , with an upper limit of  $k(x_0)$  [see diagram], and note that  $k(x)$  can't be above

$\frac{1}{320} + \frac{1}{2}k(x_0)$ , then we see that this doesn't work if  $k(x_0)$  is very large relative to  $\frac{1}{320}$ , but that it can do if  $k(x_0)$  is small enough relative to  $\frac{1}{320}$

(in general, a useful device is to consider extreme situations)

So we need to be looking for an upper limit for  $k(x_0)$ .

From (A),  $k(x) \leq \frac{1}{320} + \frac{1}{2}k(x_0)$  whenever  $0 \leq x \leq \frac{1}{2}$

In particular,  $k(x_0) \leq \frac{1}{320} + \frac{1}{2}k(x_0)$ ,

so that  $\frac{1}{2}k(x_0) \leq \frac{1}{320}$  and  $k(x_0) \leq \frac{1}{160}$

Then  $k(x) \leq k(x_0) \leq \frac{1}{160} < \frac{1}{100}$ ,

and  $k(x) \leq \frac{1}{100}$ , as required.
