

2022 MAT – Q2 (2 pages; 2/11/23)**Solution**

$$\begin{aligned}
 \text{(i) If } x^2 - 19y^2 = z, \text{ then } z^2 &= (x^2 - 19y^2)^2 \\
 &= (x^2 + 19y^2)^2 - 4x^2(19y^2) \\
 &= (x^2 + 19y^2)^2 - 19(2xy)^2, \text{ so that } N = 19
 \end{aligned}$$

(ii) 1st Part

$$\text{If } x = 13 \text{ \& } y = 3, \text{ then } z = 13^2 - 19(3)^2 = 169 - 171 = -2$$

2nd Part

$$\begin{aligned}
 \text{From (i), } z^2 &= (x^2 + 19y^2)^2 - 19(2xy)^2, \\
 \text{so that } 4 &= (169 + 171)^2 - 19(78)^2
 \end{aligned}$$

Thus the required x & y are 340 and 78.

(iii) 1st Part

$$\begin{aligned}
 4 &= (340)^2 - 19(78)^2 \Rightarrow 1 = 170^2 - 19(39)^2, \\
 \text{so that the required } x \text{ \& } y &\text{ are 170 and 39.}
 \end{aligned}$$

2nd Part

From (i), when $x^2 - 19y^2 = z$, then

$$z^2 = (x^2 + 19y^2)^2 - 19(2xy)^2,$$

$$\text{so that } 1^2 = (170^2 + 19(39)^2)^2 - 19(2(170)(39))^2$$

Thus another solution to $x^2 - 19y^2 = 1$

$$\text{is } x = 170^2 + 19(39)^2, \text{ } y = 2(170)(39)$$

$$\text{(iv) } x^2 - 25y^2 = 1 \Rightarrow (x - 5y)(x + 5y) = 1$$

Then, as x & y are whole numbers,

$$\text{either } x - 5y = 1 \text{ \& } x + 5y = 1 \text{ (A)}$$

or $x - 5y = -1$ & $x + 5y = -1$ (B)

Adding the equations in (A) gives $2x = 2$, so that $x = 1$

Adding the equations in (B) gives $2x = -2$, so that $x = -1$

Thus there are no sol'ns with $x > 1$.

(v) [Using the same idea as in (i)]

If $x^2 - 17y^2 = z$, then $z^2 = (x^2 - 17y^2)^2$

$$= (x^2 + 17y^2)^2 - 4x^2(17y^2)$$

$$= (x^2 + 17y^2)^2 - 17(2xy)^2 \quad (*)$$

[Note that we can't start with $x = 1, y = 0, z = 1$, as this only leads to a 'new' sol'n of $x = 1, y = 0$]

[In (ii), we were given initial values of $x = 13, y = 3$; presumably the corresponding values with 17 in place of 19 are intended to be fairly easy to find.]

If $y = 1$, then $x^2 - 17y^2 = x^2 - 17$, and we could try $x = 4$,

as this gives $x^2 - 17y^2 = -1$

and hence, from (*), $(-1)^2 = (x^2 + 17y^2)^2 - 17(2xy)^2$,

so that a further sol'n of $x^2 - 17y^2 = 1$ is

$$x = 4^2 + 17(1)^2 = 33 \quad \& \quad y = 2(4)(1) = 8$$

[As it turned out, the method wasn't quite the same as before, as we didn't need to divide through by anything as in (iii).]
