Rank Correlation (5 pages; 23/8/19)

## (1) Formula

(1.1) The $x$ and $y$ coordinates of each data point (of $n$ points) are replaced by their $x$ and $y$ ranks (where the smallest coordinate can be given either rank 1 or $n$, provided that the other coordinate is ranked in the same order). If the ( $x_{i}, y_{i}$ ) are now pairs of ranks, and $d_{i}=x_{i}-y_{i}$, then

Spearman's coefficient of rank correlation $\left(r_{s}\right)$ is defined as
$r_{s}=1-\frac{6 \sum d_{i}^{2}}{(n-1) n(n+1)}=1-\frac{6 \sum d_{i}^{2}}{n\left(n^{2}-1\right)}$
If the plotted ranks give rise to a strictly increasing or decreasing curve, then $r_{s}$ will be 1 or -1 .
(1.2) In fact, the Spearman formula $r_{s}=1-\frac{6 \sum d_{i}{ }^{2}}{n\left(n^{2}-1\right)}$ is just a rearrangement of the Pearson formula $\frac{s_{x y}}{\sqrt{S_{x x} S_{y y}}}$ when the data items are ranks, and so it is possible (though usually more complicated) to use the Pearson formula instead.

However, because in the case of ranked data there is no assumption of a bivariate Normal distribution, different tables apply.

## Proof

$$
S_{x x}=\sum x_{i}^{2}-\frac{\left(\sum x_{i}\right)^{2}}{n}
$$

As the $x_{i}$ are just the numbers 1 to $n$ in some order,
$\sum x_{i}{ }^{2}=\frac{n}{6}(n+1)(2 n+1)$ and $\sum x_{i}=\frac{n}{2}(n+1)$
and so $S_{x x}=\frac{n}{6}(n+1)(2 n+1)-\frac{n(n+1)^{2}}{4}$

By the same reasoning, $S_{y y}$ will also have this value,
so the denominator of $r$ is
$\frac{n}{6}(n+1)(2 n+1)-\frac{n(n+1)^{2}}{4}=\frac{n}{12}(n+1)\{4 n+2-(3 n+3)\}$
$=\frac{n}{12}(n+1)(n-1)$
Then $S_{x y}=\sum x_{i} y_{i}-\frac{\left(\sum x_{i}\right)\left(\sum y_{i}\right)}{n}$
Now $\sum{d_{i}}^{2}=\sum\left(x_{i}-y_{i}\right)^{2}=\left(\sum x_{i}^{2}\right)+\left(\sum y_{i}^{2}\right)-2 \sum x_{i} y_{i}$,
so that $\sum x_{i} y_{i}=\frac{\left(\sum x_{i}{ }^{2}\right)+\left(\sum y_{i}^{2}\right)-\sum d_{i}{ }^{2}}{2}$
$=\frac{1}{2}\left\{2 \cdot \frac{n}{6}(n+1)(2 n+1)-\sum d_{i}{ }^{2}\right\}$
Hence $S_{x y}=\frac{n}{6}(n+1)(2 n+1)-\frac{1}{2} \sum d_{i}{ }^{2}-\frac{\left(\frac{n}{2}(n+1)\right)^{2}}{n}$
$=\frac{n}{12}(n+1)\{4 n+2-(3 n+3)\}-\frac{1}{2} \sum d_{i}{ }^{2}$
$=\frac{n}{12}(n+1)(n-1)-\frac{1}{2} \sum d_{i}{ }^{2}$
and $r=\frac{\frac{n}{12}(n+1)(n-1)-\frac{1}{2} \sum d_{i}{ }^{2}}{\frac{n}{12}(n+1)(n-1)}=1-\frac{6 \sum d_{i}{ }^{2}}{n\left(n^{2}-1\right)}$

## (2) Use of the rank correlation coefficient

(2.1) It can be applied when the underlying data doesn't have a bivariate Normal distribution.
(2.2) The association of the underlying data need not be linear, but it should be a 'monotonic relationship'; ie increasing or decreasing.
(2.3) For some data, only ranks may be available (or they are easier to obtain); eg the positions awarded by judges in a competition.
(2.4) If the underlying data is available, and the conditions for PMCC are satisfied, then the PMCC provides a better test, as otherwise information is lost in converting to ranks.
(2.5) The formula isn't strictly applicable if any ranks are tied; however, it will be approximately correct if only a few ranks are tied.
(3) Hypothesis Tests
(3.1) Critical values for $r_{s}$ are slightly different from those for $r$ (because of the different assumptions regarding the bivariate Normal distribution).
(3.2) Critical Values for $r_{s}$ :

|  | $5 \%$ | $2^{1 / 2} \%$ | $1 \%$ | $1 / 2 \%$ |
| :---: | :---: | :---: | :---: | :---: |
|  | $10 \%$ | $5 \%$ | $2 \%$ | $1 \%$ |
| $n$ |  | - | - | - |
