

## Groups - Part 2 (12 pages; 23/10/16)

### (A) Cyclic Groups - Examples

Notes

(a) All cyclic groups of order  $n$  (denoted  $C_n$ ) are isomorphic.

(b) All groups of prime order are cyclic (but the converse is not true).

(1)  $(\mathbb{Z}, +)$

infinite order;  $e = 0$ ;  $a^{-1} = -a$

(2)  $\{0, 1, 2, \dots, n - 1\}$  under addition mod  $n$  (or 'modulo'  $n$ )

- commonly denoted  $(\mathbb{Z}_n, +)$

Note: it is possible to write  $a +_n b$ , but  $a + b$  is used when the modulus is understood.

For eg  $(\mathbb{Z}_4, +)$ ,  $\{0, 2\}$  is a subgroup.

(3)  $(\{1, -1\}, \times)$

(4)  $\{1, i, -1, -i\}$  under multiplication of complex numbers

	1	$i$	-1	$-i$
1	1	$i$	-1	$-i$
$i$	$i$	-1	$-i$	1
-1	-1	$-i$	1	$i$
$-i$	$-i$	1	$i$	-1

$i^2 = -1, i^3 = -i, i^4 = 1$ , so  $i$  is of order 4

$(-1)^2 = 1$ , so  $-1$  is of order 2

$(-i)^2 = -1, (-i)^3 = i, (-i)^4 = 1$ , so  $-i$  is of order 4

Thus,  $i$  &  $-i$  are generators of the group (being inverses of each other).

(5)  $\{1,2,4,8\}$  under multiplication mod 15

	1	2	4	8
1	1	2	4	8
2	2	4	8	1
4	4	8	1	2
8	8	1	2	4

(6)  $\left\{ \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}, \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \right\}$

under multiplication

$[a = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}: 90^\circ \text{ rotation clockwise}]$

$b = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}: 180^\circ \text{ rotation}]$

$c = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}: 90^\circ \text{ rotation anti-clockwise}]$

[More generally, the group generated by the rotation of a plane through  $\frac{360^\circ}{n}$  about a fixed point.]

	$e$	$a$	$b$	$c$
$e$	$e$	$a$	$b$	$c$
$a$	$a$	$b$	$c$	$e$
$b$	$b$	$c$	$e$	$a$
$c$	$c$	$e$	$a$	$b$

$a$  &  $c$  are generators of the group

$$(7) \left\{ x, -\frac{1}{x}, \frac{x-1}{x+1}, \frac{1+x}{1-x} \right\}$$

under composition of functions on  $x \in \mathbb{R}, x \neq -1, 0, 1$

$$\text{Let } a = -\frac{1}{x}, b = \frac{x-1}{x+1} \text{ \& } c = \frac{1+x}{1-x}$$

$$\text{Then } a^2 = -\frac{1}{\left(-\frac{1}{x}\right)} = x = e$$

$$\text{and } b^2 = \frac{\left(\frac{x-1}{x+1}\right)^{-1}}{\left(\frac{x-1}{x+1}\right)+1} = \frac{x-1-(x+1)}{x-1+(x+1)} = \frac{-2}{2x} = a$$

So, if this is to be a group, it must be cyclic, rather than the Klein 4-group (since all elements are of order 2 for the latter).

As  $a^2 = e$ , it is worth relabelling the elements, so that  $b = -\frac{1}{x}$

Then it doesn't matter how the other non-identity elements are labelled; eg  $a = \frac{x-1}{x+1}$  &  $c = \frac{1+x}{1-x}$ , and the Cayley table is found to be:

	$e$	$a$	$b$	$c$
$e$	$e$	$a$	$b$	$c$
$a$	$a$	$b$	$c$	$e$
$b$	$b$	$c$	$e$	$a$
$c$	$c$	$e$	$a$	$b$

(8) If  $\omega = e^{2\pi i/3}, \{1, -1, \omega, -\omega, \omega^2, -\omega^2\}$  under multiplication

## (B) Non-Cyclic Groups - Examples

(1)  $\{1, 3, 5, 7\}$  under multiplication mod 8

Note: More generally, the positive integers less than  $n$  which have no factors in common with  $n$  (with 1 included) form a group under the operation of multiplication mod  $n$ .

	1	3	5	7
1	1	3	5	7
3	3	1	7	5
5	5	7	1	3
7	7	5	3	1

Klein 4-group (as not cyclic)

Note that the similar-looking group  $\{1,2,4,8\}$  under multiplication mod 15 was found to be cyclic.

$$(2) \left\{ \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} \right\}$$

under multiplication

$$[a = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}: \text{reflection about } x\text{-axis}]$$

$$b = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}: \text{reflection about } y\text{-axis}]$$

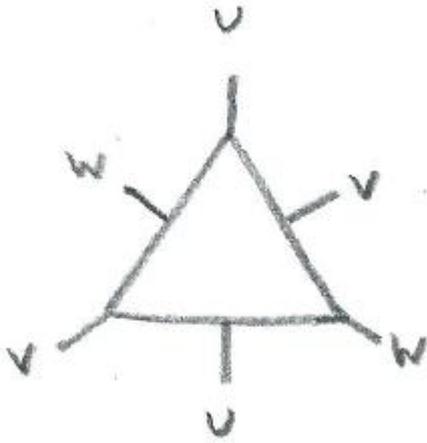

$$c = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}: 180^\circ \text{ rotation}]$$

	<i>e</i>	<i>a</i>	<i>b</i>	<i>c</i>
<i>e</i>	<i>e</i>	<i>a</i>	<i>b</i>	<i>c</i>
<i>a</i>	<i>a</i>	<i>e</i>	<i>c</i>	<i>b</i>
<i>b</i>	<i>b</i>	<i>c</i>	<i>e</i>	<i>a</i>
<i>c</i>	<i>c</i>	<i>b</i>	<i>a</i>	<i>e</i>

ie the Klein 4-group

(3) The symmetry group of an equilateral triangle,  $D_3$  has order 6. [*D* stands for 'dihedral' ("having or formed by 2 planes" - although that doesn't really explain much!)]

[More generally,  $D_n$  (the symmetry group of a regular  $n$ -sided polygon) is of order  $2n$ : in addition to the identity element, there will be  $n - 1$  rotations and  $n$  reflections.]

Let  $I$  be the identity transformation.

Let  $P$  be a rotation of  $120^\circ$  anticlockwise in the plane of the paper.

Let  $Q$  be a rotation of  $120^\circ$  clockwise in the plane of the paper.

Let  $U, V$  &  $W$  be reflections in the  $U, V$  &  $W$  axes respectively.

The Cayley table is found to be as follows:

(with the 1st transformation being along the top)

	I	P	Q	U	V	W
I	I	P	Q	U	V	W
P	P	Q	I	W	U	V
Q	Q	I	P	V	W	U
U	U	V	W	I	P	Q
V	V	W	U	Q	I	P
W	W	U	V	P	Q	I

The following observations can be made:

(i) The group is non-abelian.

(ii)  $U, V$  &  $W$  are of order 2.

(iii)  $P^3 = P(P^2) = PQ = I$  and  $Q^3 = Q(Q^2) = QP = I$ , so that both  $P$  &  $Q$  are of order 3. And  $\{I, P, Q\}$  is a subgroup.

(Note that, whilst  $U, V$  &  $W$  don't appear in the section of the table with rows and columns of  $I, P$  &  $Q$ , the reverse isn't true:  $P$  &  $Q$  do appear in the remainder of the table.)

(4) Permutations of  $(1, 2, 3, \dots, n)$

eg (for  $n = 5$ )  $\begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 4 & 3 & 5 & 2 & 1 \end{pmatrix}$  is a possible permutation.

Denoted  $S_n$  ( $S$  stands for symmetric - though the origin of this isn't clear).

The order is  $n!$  ( $n$  ways of choosing the 1st entry of the 2nd row,  $n - 1$  ways of choosing the 2nd entry etc)

(By convention, the top row is ordered.)

To find inverse permutations, simply swap the two rows and then order the top row.

For  $n = 3$ , the elements of the group are

$$e = \begin{pmatrix} 1 & 2 & 3 \\ 1 & 2 & 3 \end{pmatrix}, a = \begin{pmatrix} 1 & 2 & 3 \\ 1 & 3 & 2 \end{pmatrix}, b = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \end{pmatrix}$$

$$c = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \end{pmatrix}, d = \begin{pmatrix} 1 & 2 & 3 \\ 3 & 1 & 2 \end{pmatrix}, f = \begin{pmatrix} 1 & 2 & 3 \\ 3 & 2 & 1 \end{pmatrix}$$

$$a^2 = \begin{pmatrix} 1 & 2 & 3 \\ 1 & 3 & 2 \\ 1 & 2 & 3 \end{pmatrix} = e, b^2 = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \\ 1 & 2 & 3 \end{pmatrix} = e$$

$$c^2 = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \\ 3 & 1 & 2 \end{pmatrix} = d, d^2 = \begin{pmatrix} 1 & 2 & 3 \\ 3 & 1 & 2 \\ 2 & 3 & 1 \end{pmatrix} = c$$

$$f^2 = \begin{pmatrix} 1 & 2 & 3 \\ 3 & 2 & 1 \\ 1 & 2 & 3 \end{pmatrix} = e$$

$$c^3 = c(c^2) = \begin{pmatrix} 1 & 2 & 3 \\ 3 & 1 & 2 \\ 1 & 2 & 3 \end{pmatrix} = e, \quad d^3 = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \\ 1 & 2 & 3 \end{pmatrix} = e$$

All groups of order 6 are either cyclic or isomorphic to  $D_3$ . As none of the elements has order 6,  $S_3$  cannot be cyclic. Comparing with  $D_3$ , and relabelling, the two elements of order 3,  $c$  &  $d$  need to be  $P$  &  $Q$  (or the other way round); noting that  $c$  &  $d$  are the cyclic permutations of  $(1,2,3)$ .

Then, we can establish that  $af = c$ , so that we want  $a, b$  &  $f$  to become  $U, W$  &  $V$ , respectively (as  $UV = P$ ).

$$(5) \left\{ x, 1-x, \frac{1}{x}, \frac{1}{1-x}, \frac{x-1}{x}, \frac{x}{x-1} \right\}$$

under composition of functions on  $x \in \mathbb{R}, x \neq 0,1$

$$\text{Let } e = x, a = 1-x, b = \frac{1}{x}, c = \frac{1}{1-x}, d = \frac{x-1}{x}, f = \frac{x}{x-1}$$

	<b>e</b>	<b>a</b>	<b>b</b>	<b>c</b>	<b>d</b>	<b>f</b>
<b>e</b>	e	a	b	c	d	f
<b>a</b>	a	e	d	f	b	c
<b>b</b>	b	c	e	a	f	d
<b>c</b>	c	b	f	d	e	a
<b>d</b>	d	f	a	e	c	b
<b>f</b>	f	d	c	b	a	e

This group is non-abelian.

$$a^2 = e, \text{ so } a \text{ is of order 2}$$

$$b^2 = e, \text{ so } b \text{ is of order 2}$$

$$c^2 = d, \quad c^3 = c(c^2) = cd = e \text{ so } c \text{ is of order 3}$$

[note that  $c(c^2) = c(c)(c) = (c^2)c$ , by associativity, so that

$cd = dc$  (even though the group isn't abelian)]

$d^2 = c, d^3 = d(d^2) = dc = e$  so  $d$  is of order 3

$f^2 = e$ , so  $f$  is of order 2

Subgroups:  $\{e, a\}, \{e, b\}, \{e, f\}, \{e, c, d\}$

By re-labelling, we can see that this group is isomorphic to  $D_3$ :

Rewrite  $e$  as  $I, c$  as  $P, d$  as  $Q, a$  as  $U, f$  as  $V$  &  $b$  as  $W$

(since  $af = c$  &  $UV = P$ )

(6) Symmetries of a square (order 8), with the following subgroups:

4 reflections (each of order 2)

rotation through 180 (order 2)

rotations through  $90^\circ$  or  $-90^\circ$  (each of order 4)

## (C) Summaries of Results

### Groups of Order 4

(1) All groups of order 4 are either cyclic or are the Klein 4-group.

(2) Cyclic groups of order 4 have the following structure:

	$e$	$a$	$b$	$c$
$e$	$e$	$a$	$b$	$c$
$a$	$a$	$b$	$c$	$e$
$b$	$b$	$c$	$e$	$a$
$c$	$c$	$e$	$a$	$b$

Alternative form:

	$e$	$a$	$a^2$	$a^3$
$e$	$e$	$a$	$a^2$	$a^3$
$a$	$a$	$a^2$	$a^3$	$e$

$a^2$	$a^2$	$a^3$	$e$	$a$
$a^3$	$a^3$	$e$	$a$	$a^2$

The only proper subgroup is:  $\{e, a^2\}$

(3) The Klein 4-group has the following structure:

	$e$	$a$	$b$	$c$
$e$	$e$	$a$	$b$	$c$
$a$	$a$	$e$	$c$	$b$
$b$	$b$	$c$	$e$	$a$
$c$	$c$	$b$	$a$	$e$

Alternative form:

	$e$	$a$	$b$	$ab$
$e$	$e$	$a$	$b$	$ab$
$a$	$a$	$e$	$ab$	$b$
$b$	$b$	$ab$	$e$	$a$
$ab$	$ab$	$b$	$a$	$e$

(4) Both these types are abelian.

## Groups of Order 6

(1) All groups of order 6 are either cyclic (and therefore abelian) or isomorphic to  $D_3$  (symmetries of an equilateral triangle) (and therefore non-abelian).

(2) Cyclic groups of order 6 have the following proper subgroups:  
 $\{e, a^2, a^4\}$  and  $\{e, a^3\}$

(3) The  $D_3$  group has the following structure:

	I	P	Q	U	V	W
I	I	P	Q	U	V	W
P	P	Q	I	W	U	V
Q	Q	I	P	V	W	U
U	U	V	W	I	P	Q
V	V	W	U	Q	I	P
W	W	U	V	P	Q	I

## Cyclic Groups

(1) All groups of prime order are isomorphic to each other; being cyclic. Therefore they are isomorphic to  $(\mathbb{Z}_n, +)$ .

(2) All cyclic groups are abelian.

(3) A cyclic group of order  $n$  (whether  $n$  is prime or not) can always be created from  $\{0, 1, 2, \dots, n - 1\}$  under addition mod  $n$ .

(4)  $C_n$  is isomorphic to the group generated by the rotation of a plane through  $\frac{2\pi}{n}$ , and thus cyclic groups of all orders exist.

(5) A group of order  $n$  is cyclic if it contains an element of order  $n$ .

(6) Any subgroup of a cyclic group must also be cyclic.

(7) For each factor  $f$  of the order  $n$  of a cyclic group, there will be a subgroup of order  $f$ .

For example, the proper subgroups of the cyclic group of order 12 are:  $\{e, a^2, a^4, a^6, a^8, a^{10}\}$ ,  $\{e, a^3, a^6, a^9\}$ ,  $\{e, a^4, a^8\}$ ,  $\{e, a^6\}$

## Abelian Groups

(1) A group that contains no elements of order greater than 2 (ie where every element is its own inverse) must be abelian.

(2) All cyclic groups are abelian.

(3) Klein 4-groups are abelian.

(4) All groups of order 4 are abelian.

## Subgroups

- (1) Lagrange's theorem: The order of a subgroup of a finite group is a factor of the order of the group.
- (2) From Lagrange's theorem, groups of prime order have no subgroups.
- (3) Let  $a$  be an element of a group  $G$ . Then  $\{a^n : n \in \mathbb{Z}\}$  is a subgroup of  $G$  (referred to as the subgroup generated by  $a$ ). This is an easy way of finding a subgroup.
- (4) If  $H$  is a non-empty subset of  $G$ , then if  $ab^{-1} \in H \forall a, b \in H$ , then  $H$  is a subgroup of  $G$
- (5) Any subgroup of a cyclic group must also be cyclic.

## Elements of Groups

- (1) The order of an element divides the order of the group.
- (2) Let  $a$  be an element of a group  $G$ . Then  $\{a^n : n \in \mathbb{Z}\}$  is a subgroup of  $G$  (referred to as the subgroup generated by  $a$ ). This is an easy way of finding a subgroup.
- (3) If  $g$  is a generator of a group, then  $g^{-1}$  will be also.
- (4) If  $g$  is a generator of a group of order  $n$ , then  $g^k$  will be also if and only if  $k$  and  $n$  are co-prime (ie have no common factors).
- (5) Every element of a group of prime order is a generator of the group.

## Isomorphisms

- (1) All groups of prime order are isomorphic to each other; being cyclic. Therefore they are isomorphic to  $(\mathbb{Z}_n, +)$ .
- (2) Groups of order 4 are either cyclic, or have 3 elements of order 2 (the Klein 4-group).

(3) Cayley's theorem: Any group of order  $n$  is isomorphic to a subgroup of  $S_n$  (the group of permutations of  $(1,2,3, \dots, n)$ ).

(D) Table of possibilities

Order	Cyclic?	Abelian?	Proper Subgroups?	Notes
4	Y	Y	Y	$C_4$
4	N	Y	Y	Klein 4-group
