

STEP 2001, Paper 2, Q11 (4 pages; 30/3/25)

- 11 A two-stage missile is projected from a point A on the ground with horizontal and vertical velocity components u and v , respectively. When it reaches the highest point of its trajectory an internal explosion causes it to break up into two fragments. Immediately after this explosion one of these fragments, P , begins to move vertically upwards with speed v_e , but retains the previous horizontal velocity. Show that P will hit the ground at a distance R from A given by

$$\frac{gR}{u} = v + v_e + \sqrt{(v_e^2 + v^2)}.$$

It is required that the range R should be greater than a certain distance D (where $D > 2uv/g$). Show that this requirement is satisfied if

$$v_e > \frac{gD}{2u} \left(\frac{gD - 2uv}{gD - uv} \right).$$

[The effect of air resistance is to be neglected.]

1st Part

Let d_1 & d_2 be the horizontal distances covered before and after the explosion (so that $R = d_1 + d_2$).

Also, let T_1 & T_2 be the times taken to cover these distances.

Then, if H is the maximum height reached by the missile (before the explosion), the suvat equation ' $v^2 = u^2 + 2as$ ' applied to the vertical component of motion gives

$$0 = v^2 + 2(-g)H, \text{ so that } H = \frac{v^2}{2g} \quad (1)$$

Also, ' $v = u + at$ ' (again, vertically) gives $0 = v + (-g)T_1$,

$$\text{and (horizontally) } d_1 = uT_1 = u \frac{v}{g} \quad (2)$$

Then, after the explosion, ' $s = s_0 + ut + \frac{1}{2}at^2$ ' (vertically) gives (with upwards as the positive direction):

$$0 = H + v_e T_2 + \frac{1}{2}(-g)T_2^2 \quad (*)$$

$$\text{and (horizontally) } d_2 = uT_2 \quad (3)$$

Then, from (*), $gT_2^2 - 2v_e T_2 - 2(\frac{v^2}{2g}) = 0$, from (1),

$$\text{so that } T_2 = \frac{2v_e + \sqrt{4v_e^2 + 4v^2}}{2g} \text{ (taking the positive root)}$$

$$= \frac{v_e + \sqrt{v_e^2 + v^2}}{g} \quad (4)$$

$$\text{And so } \frac{gR}{u} = \frac{g}{u}(d_1 + d_2) = v + gT_2, \text{ from (2) \& (3),}$$

$$= v + v_e + \sqrt{v_e^2 + v^2}, \text{ from (4), as required.}$$

2nd Part

[The fact that $D > \frac{2uv}{g}$ means that both $Dg - 2uv$ & $Dg - uv$ are positive, so that the lower limit for v_e that we are being asked to establish is a positive value. (If it were negative, it would automatically be satisfied.)]

The requirement that $R > D$ is equivalent to $\frac{gR}{u} > \frac{gD}{u}$,

or $\frac{gR}{u} > D'$, where $D' = \frac{gD}{u}$ (1)

And $v_e > \frac{gD}{2u} (\frac{gD-2uv}{gD-uv})$ is equivalent to $v_e > \frac{D'}{2} (\frac{D'-2v}{D'-v})$ (2)

Also, from the 1st Part, (1) is equivalent to

$$v + v_e + \sqrt{v_e^2 + v^2} > D' \quad (1')$$

Result to prove: (2) \Rightarrow (1')

$$\text{Now, } (1') \Leftrightarrow \sqrt{v_e^2 + v^2} > D' - v - v_e \quad (A)$$

$$\text{Consider (B): } v_e^2 + v^2 > (D' - v - v_e)^2$$

$$\text{As } \sqrt{v_e^2 + v^2} \geq 0, (B) \Rightarrow (A) \text{ [whether or not } D' - v - v_e > 0]$$

$$\text{[though (B) } \nRightarrow (A), \text{ as it may be the case that } D' - v - v_e > 0]$$

So, result to prove is now: (2) \Rightarrow (B)

(then, from the above, (2) \Rightarrow (B) \Rightarrow (A) \Rightarrow (1')).

$$\text{where (2) is: } v_e > \frac{D'}{2} (\frac{D'-2v}{D'-v}) ,$$

and (B) is $v_e^2 + v^2 > (D' - v - v_e)^2$, which is equivalent to

$$0 > (D')^2 - 2D'v - 2D'v_e + 2vv_e \quad (B')$$

And (2): $v_e > \frac{D'}{2} \left(\frac{D'-2v}{D'-v} \right)$ is equivalent to

$$2v_e(D' - v) > (D')^2 - 2D'v$$

(as $D' - v > 0$, given that $D > \frac{2uv}{g}$, so that $D' = \frac{gD}{u} > 2v > v$),

which is equivalent to (B') .

Thus, in particular, $(2) \Rightarrow (B') \equiv (B)$, as required.
